Study Guide: Data Retrieval with SQL

Afshine Amidi and Shervine Amidi

August 14, 2020

General concepts

- $\hfill \square$ Structured Query Language Structured Query Language, abbreviated as SQL, is a language that is largely used in the industry to query data from databases.
- □ Query structure Queries are usually structured as follows:

SQL —		_
Select fields SELECT col_1, col_2,, col_n	mandatory	
Source of data FROM table t	mandatory	
Gather info from other sources JOIN other_table ot ON (t.key = ot.key)	optional	
Conditions WHERE some_condition(s)	optional	
Aggregating GROUP BY column_group_list	optional	
Sorting values ORDER BY column_order_list	optional	
Restricting aggregated values HAVING some_condition(s)	optional	
Limiting number of rows LIMIT some_value	optional	ر

Remark: the SELECT DISTINCT command can be used to ensure not having duplicate rows.

□ Condition – A condition is of the following format:

```
SQL some_col some_operator some_col_or_value
```

where some_operator can be among the following common operations:

Category	Operator	Command
	Equality / non-equality	= / !=, <>
	Inequalities	>=, >, <, <=
General	Belonging	IN (val_1,, val_n)
General	And / or	AND / OR
	Check for missing value	IS NULL
	Between bounds	BETWEEN val_1 AND val_2
Strings	Pattern matching	LIKE '%val%'

 \square Joins – Two tables table_1 and table_2 can be joined in the following way:

```
FROM table_1 t1
type_of_join table_2 t2
ON (t2.key = t1.key)
...
```

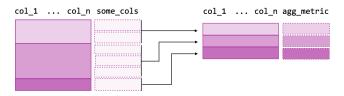

where the different type_of_join commands are summarized in the table below:

Type of join	Illustration	
INNER JOIN	t1 t2	
LEFT JOIN	t1 t2	
RIGHT JOIN	t1 t2	
FULL JOIN	t1 t2	

Remark: joining every row of table 1 with every row of table 2 can be done with the CROSS JOIN command, and is commonly known as the cartesian product.

Aggregations

 $\hfill\Box$ Grouping data – Aggregate metrics are computed on grouped data in the following way:

The SQL command is as follows:

```
SQL

SELECT

col_1,
agg_function(col_2)

FROM table
GROUP BY col_1
```

 \square Grouping sets – The GROUPING SETS command is useful when there is a need to compute aggregations across different dimensions at a time. Below is an example of how all aggregations across two dimensions are computed:

 \square Aggregation functions – The table below summarizes the main aggregate functions that can be used in an aggregation query:

Category	Operation	Command
	Mean	AVG(col)
	Percentile	PERCENTILE_APPROX(col, p)
Values	Sum / # of instances	SUM(col) / COUNT(col)
	Max / min	MAX(col) / MIN(col)
	Variance / standard deviation	VAR(col) / STDEV(col)
Arrays	Concatenate into array	collect_list(col)

Remark: the median can be computed using the PERCENTILE_APPROX function with p equal to 0.5.

 \square Filtering – The table below highlights the differences between the WHERE and HAVING commands:

WHERE	HAVING
- Filter condition applies to individual rows	- Filter condition applies to aggregates
- Statement placed right after FROM	- Statement placed right after GROUP BY

Remark: if WHERE and HAVING are both in the same query, WHERE will be executed first.

Window functions

 $\hfill \Box$ Definition – A window function computes a metric over groups and has the following structure:

The SQL command is as follows:

SQL some_window_function() OVER(PARTITION BY some_col ORDER BY another_col)

Remark: window functions are only allowed in the SELECT clause.

□ Row numbering – Ranks each row across specified groups, ordered by a specific field. The table below summarizes the main commands:

Command	Description	Example
ROW_NUMBER()	Ties are given different ranks	1, 2, 3, 4
RANK()	Ties are given same rank and skip numbers	1, 2, 2, 4
DENSE_RANK()	Ties are given same rank and don't skip numbers	1, 2, 2, 3

 $\hfill\Box$ Values – The following window functions allow to keep track of specific types of values with respect to the partition:

Command	Description
FIRST_VALUE(col)	Takes the first value of the column
LAST_VALUE(col)	Takes the last value of the column
LAG(col, n)	Takes the n^{th} previous value of the column
LEAD(col, n)	Takes the n^{th} following value of the column
NTH_VALUE(col, n)	Takes the $n^{\rm th}$ value of the column

Advanced functions

 $\hfill \square$ SQL tips – In order to keep the query in a clear and concise format, the following tricks are often done:

Operation	Command	Description
Renaming columns SELECT operation_on_column AS col_name		New column names shown in query results
Abbreviating tables	FROM table_1 t1	Abbreviation used within query for simplicity in notations
Simplifying group by	GROUP BY col_number_list	Specify column position in SELECT clause instead of whole column names
Limiting results	LIMIT n	Display only n rows

 \square Sorting values – The query results can be sorted along a given set of columns using the following command:

```
SQL
... [query] ...
ORDER BY col_list
```

Remark: by default, the command sorts in ascending order. If we want to sort it in descending order, the DESC command needs to be used after the column.

 \Box Column types – In order to ensure that a column or value is of one specific data type, the following command is used:

```
CAST(some_col_or_value AS data_type)
```

where data_type is one of the following:

Data type	Description	Example
INT	Integer	2
DOUBLE	Numerical value	2.0
STRING	String	
VARCHAR	String	
DATE	Date	'2020-01-01'
TIMESTAMP	Timestamp	'2020-01-01 00:00:00.000'

Remark: if the column contains data of different types, the $TRY_CAST()$ command will convert unknown types to NULL instead of throwing an error.

□ Column manipulation – The main functions used to manipulate columns are described in the table below:

Category	Operation	Command
	Take first non-NULL value	COALESCE(col_1, col_2,, col_n)
General	Create a new column combining existing ones	CONCAT(col_1,, col_n)
Value	Round value to n decimals	ROUND(col, n)
	Converts string column to lower / upper case	LOWER(col) / UPPER(col)
String	Replace occurrences of old in col to new	REPLACE(col, old, new)
String	Take the substring of col, with a given start and length	SUBSTR(col, start, length)
	Remove spaces from the left / right / both sides	LTRIM(col) / RTRIM(col) / TRIM(col)
Date	Truncate at a given granularity (year, month, week)	DATE_TRUNC(time_dimension, col_date)
	Transform date	DATE_ADD(col_date, number_of_days)

 \square Conditional field – A column can take different values with respect to a particular set of conditions with the CASE WHEN command as follows:

```
CASE WHEN some_condition THEN some_value

...

WHEN some_other_condition THEN some_other_value
ELSE some_other_value_n END
```

 \square Combining results – The table below summarizes the main ways to combine results in queries:

Category	Command	Remarks
	UNION	Guarantees distinct rows
Union	UNION ALL	Potential newly-formed duplicates are kept
Intersection	INTERSECT	Keeps observations that are in all selected queries

□ Common table expression – A common way of handling complex queries is to have temporary result sets coming from intermediary queries, which are called common table expressions (abbreviated CTE), that increase the readability of the overall query. It is done thanks to the WITH ... AS ... command as follows:

```
WITH cte_1 AS (
SELECT ...
),
```

```
cte_n AS (
SELECT ...
)

SELECT ...
FROM ...
```

Table manipulation

☐ **Table creation** – The creation of a table is done as follows:

where [table_type], [creation_type] and [options] are one of the following:

Category	Command	Description
m.11.	Blank	Default table
Table type	EXTERNAL TABLE	External table
Creation type	Blank	Creates table and overwrites current one if it exists
	IF NOT EXISTS	Only creates table if it does not exist
Options	location 'path_to_hdfs_folder'	Populate table with data from hdfs folder
	stored as data_format	Stores the table in a specific data format, e.g. parquet, orc or avro

 \square Data insertion – New data can either append or overwrite already existing data in a given table as follows:

```
SQL

WITH ... -- optional

INSERT [insert_type] table_name -- mandatory

SELECT ...; -- mandatory
```

where [insert_type] is among the following:

```
Command Description

OVERWRITE Overwrites existing data

INTO Appends to existing data
```

□ Dropping table – Tables are dropped in the following way:

```
DROP TABLE table_name;
```

 \square View – Instead of using a complicated query, the latter can be saved as a view which can then be used to get the data. A view is created with the following command:

```
CREATE VIEW view_name AS complicated_query;
```

Remark: a view does not create any physical table and is instead seen as a shortcut.
